LSND Signal

- LSND experiment
- Stopped pion beam
 $\pi^+ \rightarrow \mu^+ + \nu_\mu$
 $\quad \quad \quad \hookrightarrow e^+ + \bar{\nu}_\mu + \nu_e$
- Excess of $\bar{\nu}_e$ in $\bar{\nu}_\mu$ beam
- $\bar{\nu}_e$ signature: Cherenkov light from e^+ with delayed γ from n-capture
- Excess = $87.9 \pm 22.4 \pm 6$ (3.8σ)

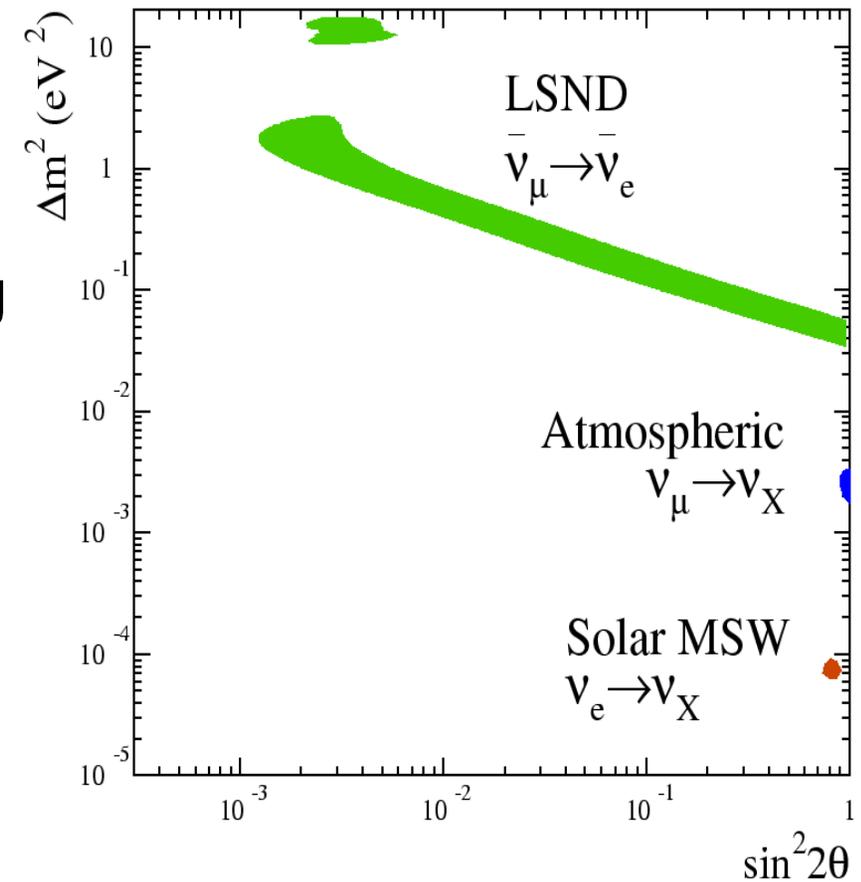

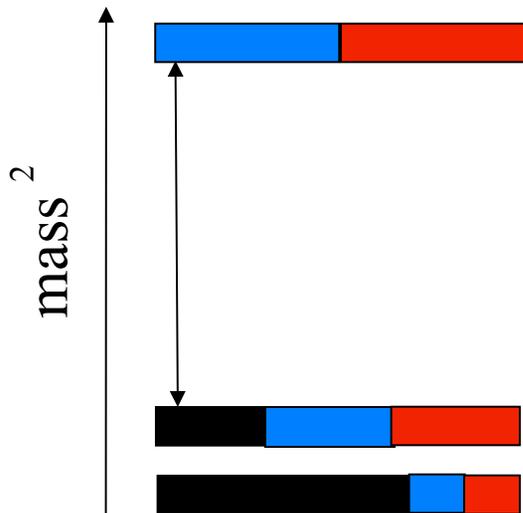

LSND Signal

- Assuming two neutrino oscillations

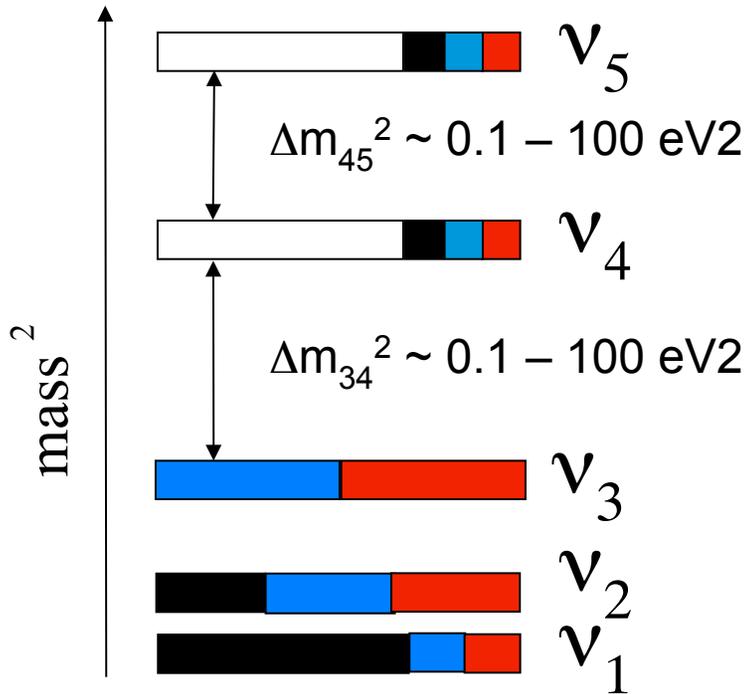

$$P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e) = \sin^2(2\theta) \sin^2\left(\frac{1.27 L \Delta m^2}{E}\right)$$

$$= 0.245 \pm 0.067 \pm 0.045 \%$$

- Can't reconcile LSND result with atmospheric and solar neutrino using only 3 Standard Model neutrinos – only two independent mass splittings

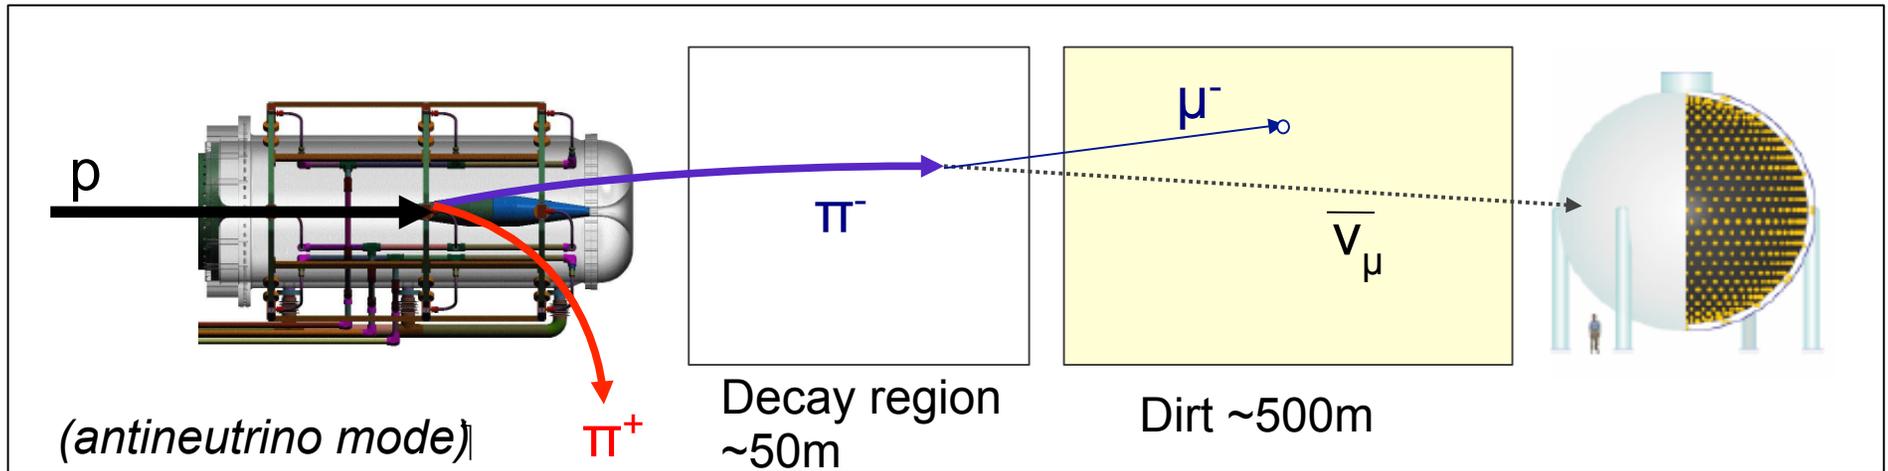

Sterile Neutrinos

- 3+N models
- For $N > 1$, model allows CP violation for short baseline
 - $\nu_\mu \rightarrow \nu_e \neq \bar{\nu}_\mu \rightarrow \bar{\nu}_e$

MiniBooNE Experiment

- Similar L/E as LSND
 - MiniBooNE $\sim 500\text{m}/\sim 500\text{MeV}$
 - LSND $\sim 30\text{m}/\sim 30\text{MeV}$
- Horn focused neutrino beam ($p+\text{Be}$)
 - Horn polarity \rightarrow neutrino or anti-neutrino mode
- 800t mineral oil Cherenkov detector

Extremely surprising result - CCQE $\sigma_{\nu_\mu}(^{12}\text{C}) > 6 \sigma_{\nu_\mu}(n)$

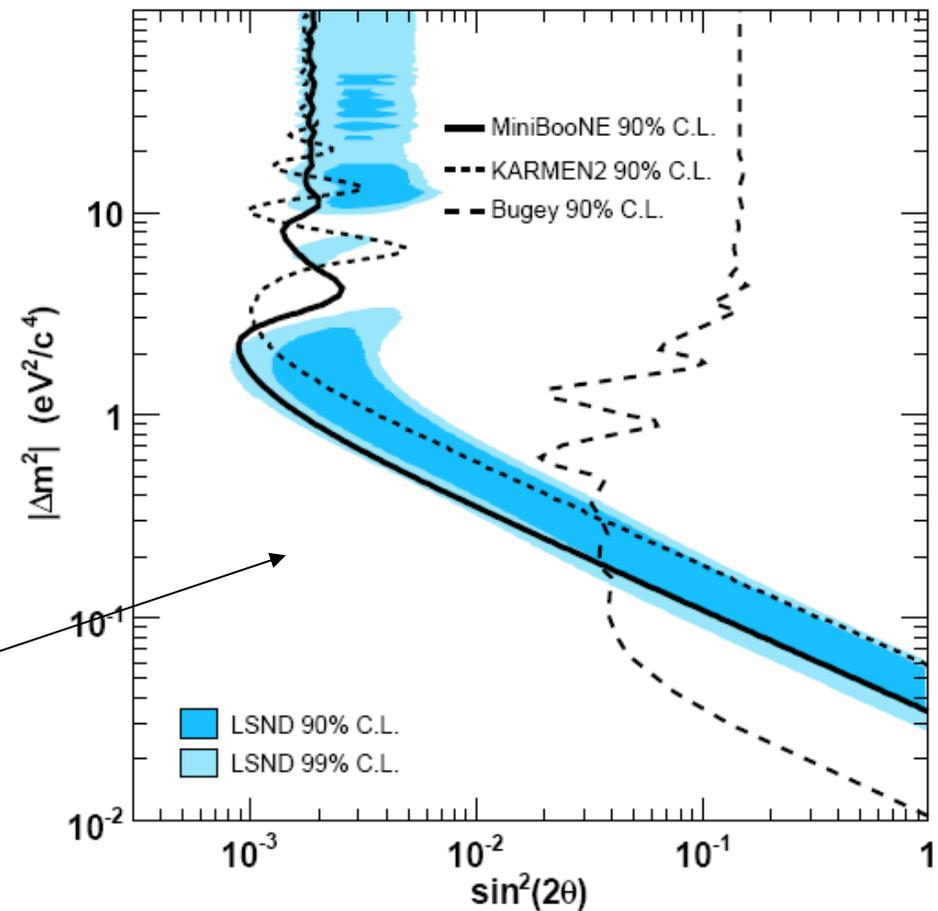

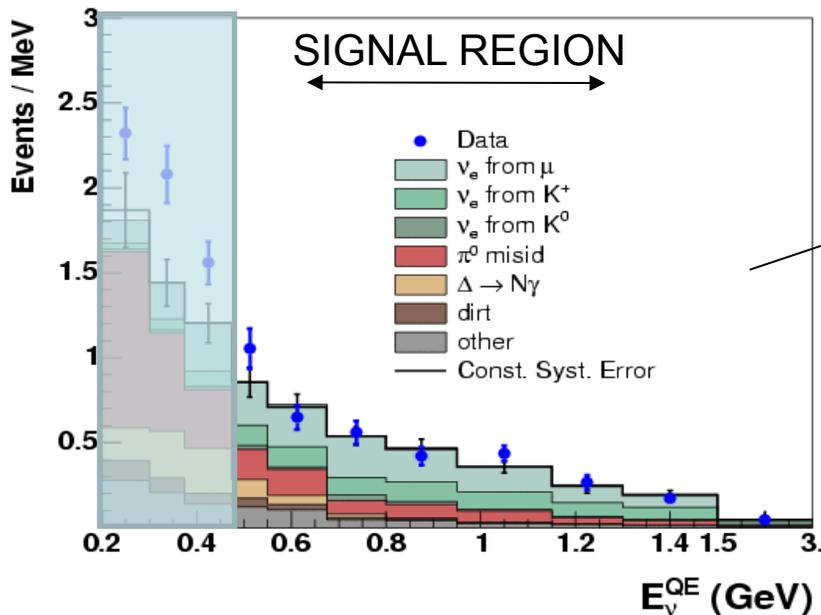

How can this be? Not seen before, requires correlations. Fermi Gas has no correlations and should be an overestimate.

A possible explanation involves short-range correlations & 2-body pion-exchange currents: Joe Carlson et al., Phys.Rev.**C65**, 024002 (2002) & Gerry Garvey.

Abstract

A three-parameter model of neutrino oscillations based on a simple Lorentz- and CPT-violating texture is presented. The model is consistent with established data and naturally generates low-energy and neutrino-antineutrino anomalies of the MiniBooNE type. Texture enhancements accommodate the LSND signal and the MINOS anomaly.

$\bar{\nu}_\mu \rightarrow \bar{\nu}_e$	18.5/6	0.5%

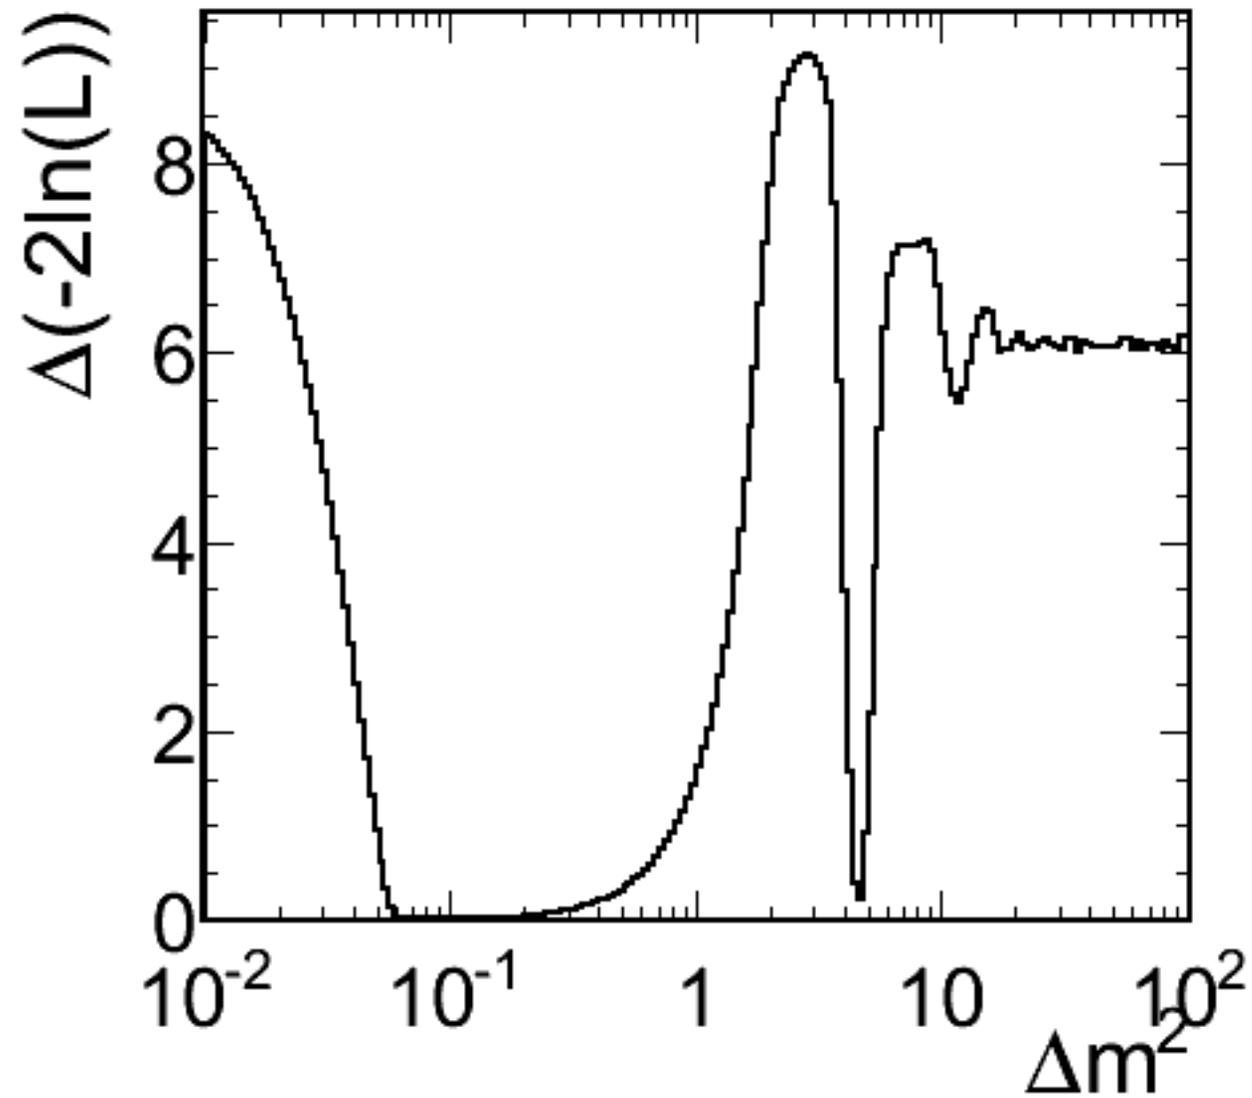

MiniBooNE Oscillation Fit E>475

- 5.66E20 POT
- E>475 is signal region for LSND type osc.
- Oscillations favored over background only hypotheses at 99.4% CL (model dependent)
- Best fit $(\sin^2 2\theta, \Delta m^2) = (0.9584, 0.064 \text{ eV}^2)$
 $\chi^2/\text{NDF} = 8.0/4$; Prob. = 8.7% (475-1250 MeV)

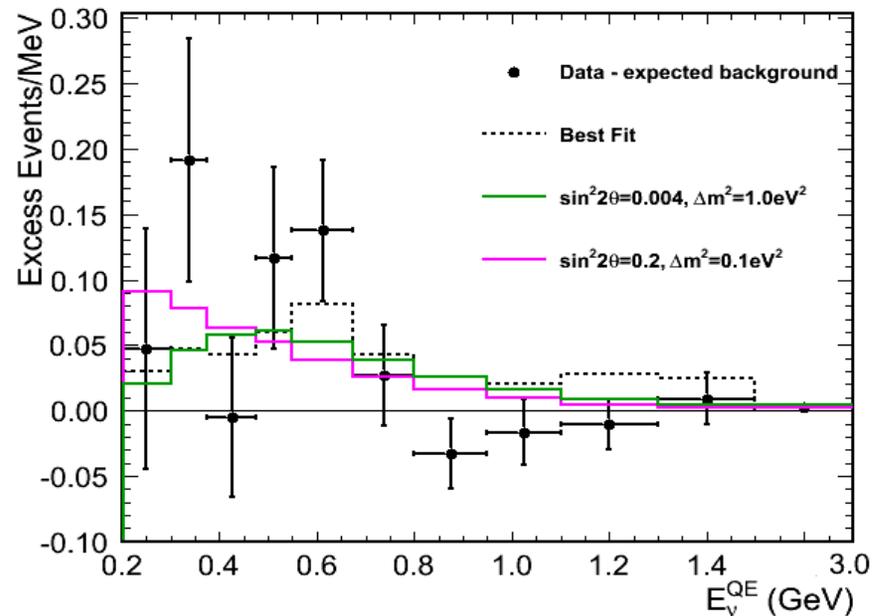

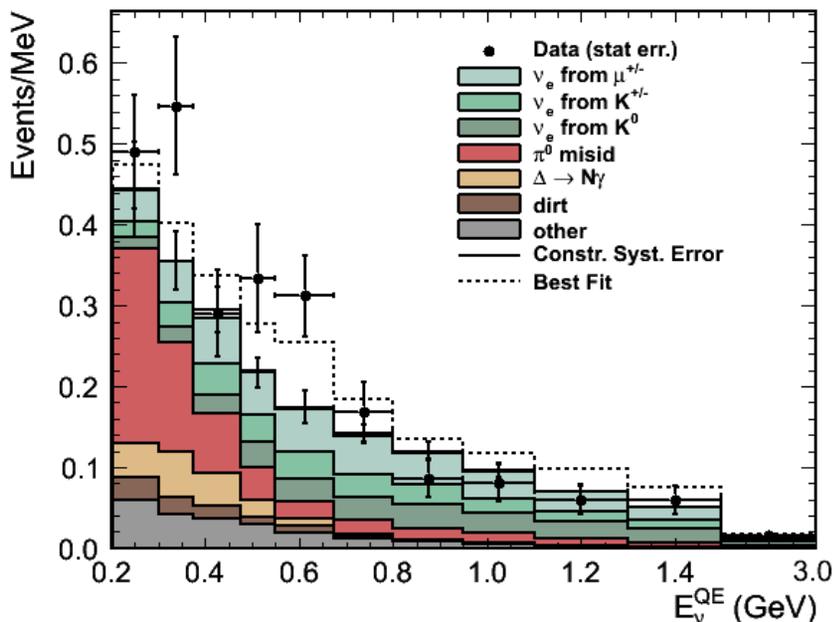

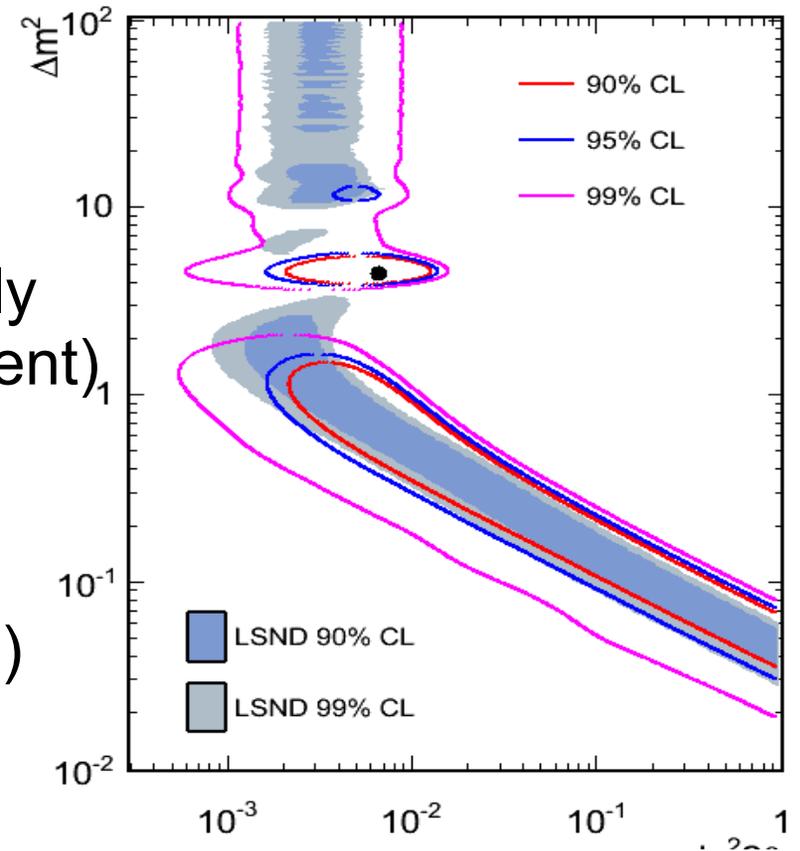

$\Delta\chi^2$ vs Δm^2

$E > 200 \text{ MeV}$

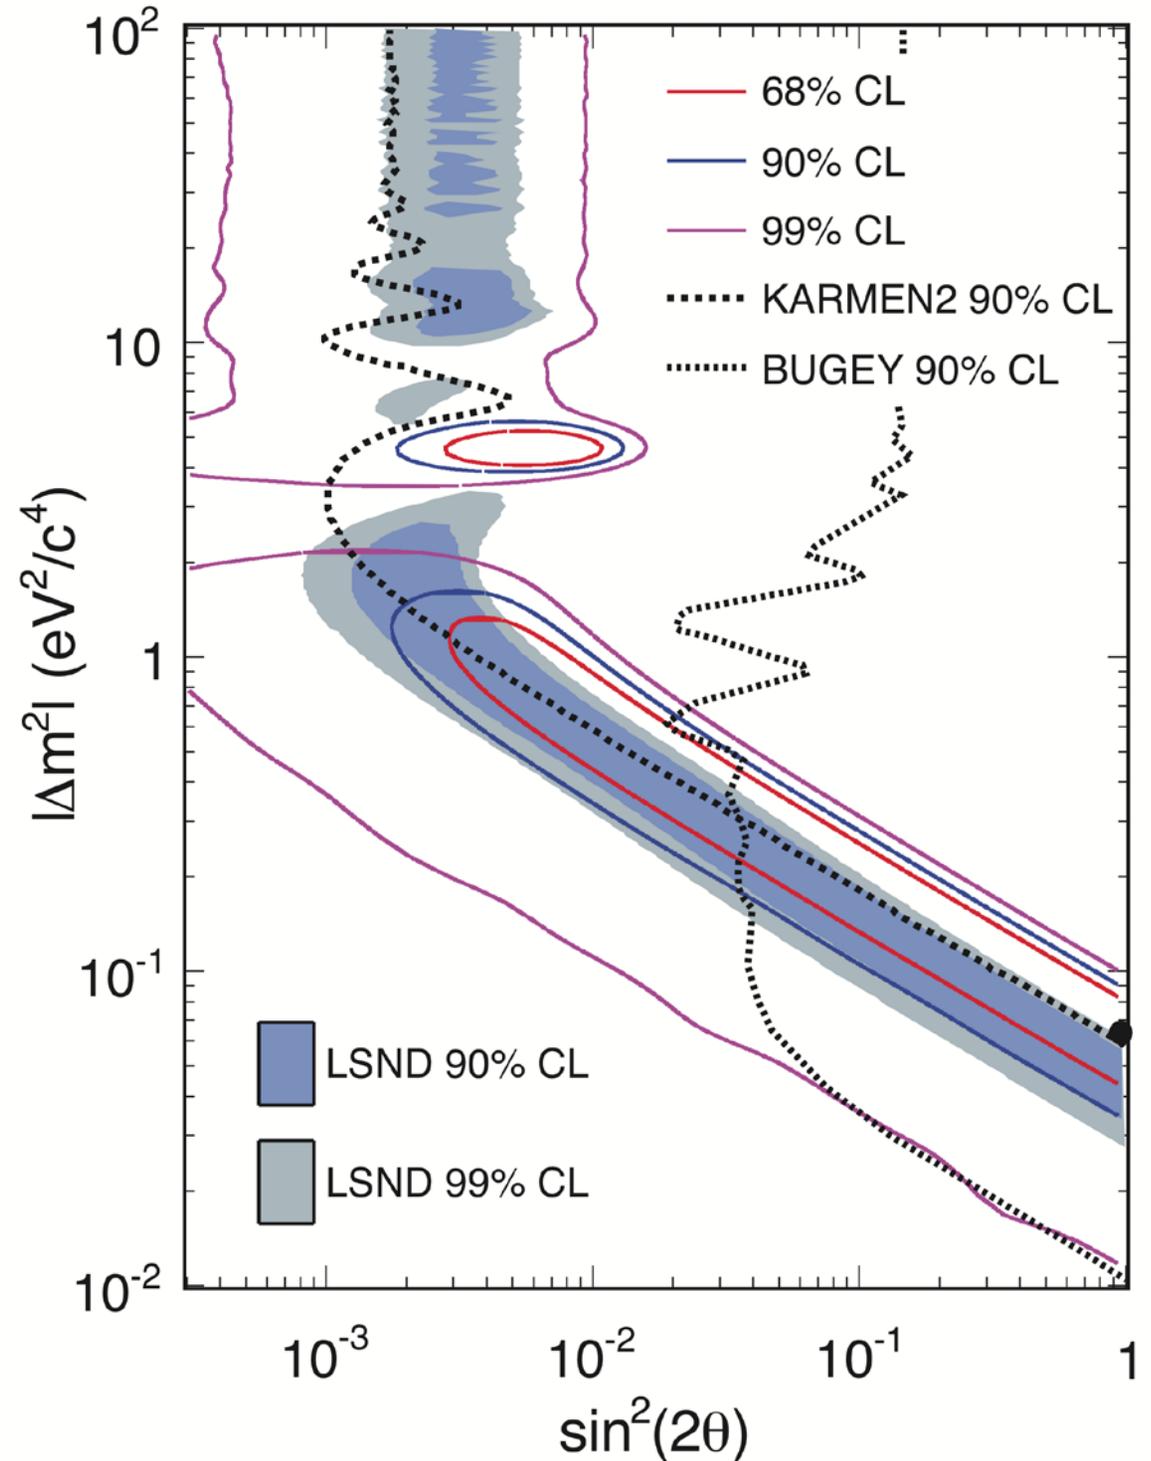

- 5.66E20 POT
- Oscillations favored over background only hypotheses at 99.6% CL (model dependent),₁
- No assumption made about low energy excess
- Best fit $(\sin^2 2\theta, \Delta m^2) = (0.0066, 4.42 \text{ eV}^2)$
 $\chi^2/\text{NDF} = 11.6/7$; Prob.=10.9%

3+N Models Requires Large $\bar{\nu}$ Disappearance!

In general, $P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e) < \frac{1}{4} P(\bar{\nu}_\mu \rightarrow \bar{\nu}_x) P(\bar{\nu}_e \rightarrow \bar{\nu}_x)$

Reactor Experiments: $P(\bar{\nu}_e \rightarrow \bar{\nu}_x) \sim 10\%$

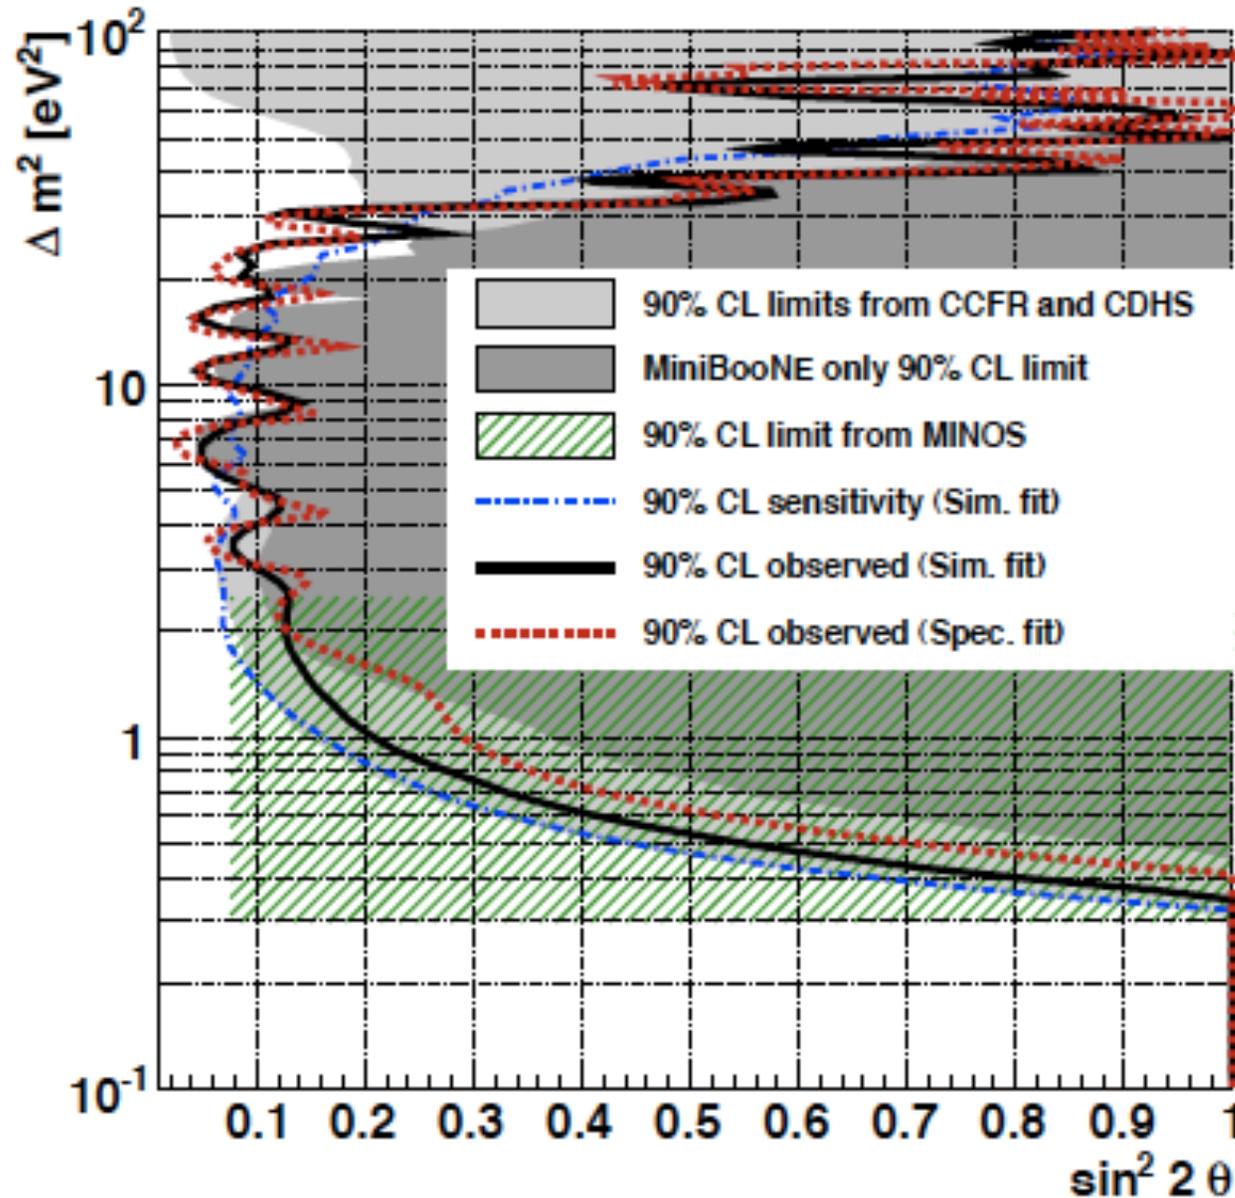

LSND/MiniBooNE: $P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e) \sim 0.25\%$

Therefore: **$P(\bar{\nu}_\mu \rightarrow \bar{\nu}_x) > 10\%$**

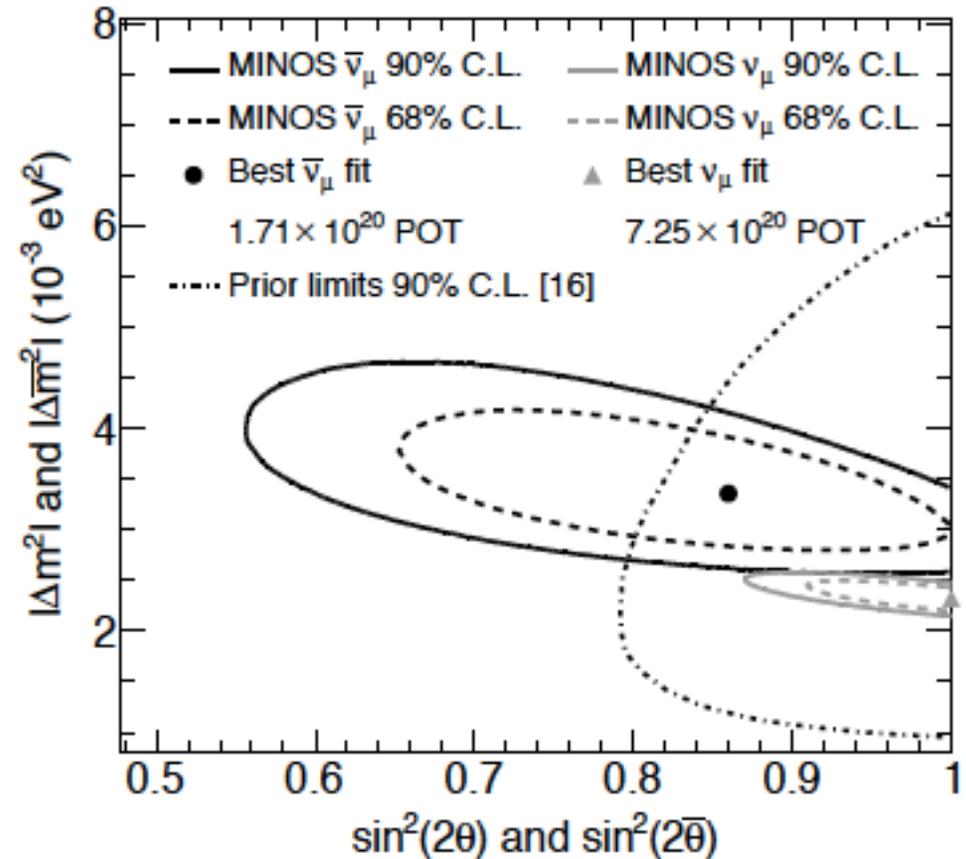

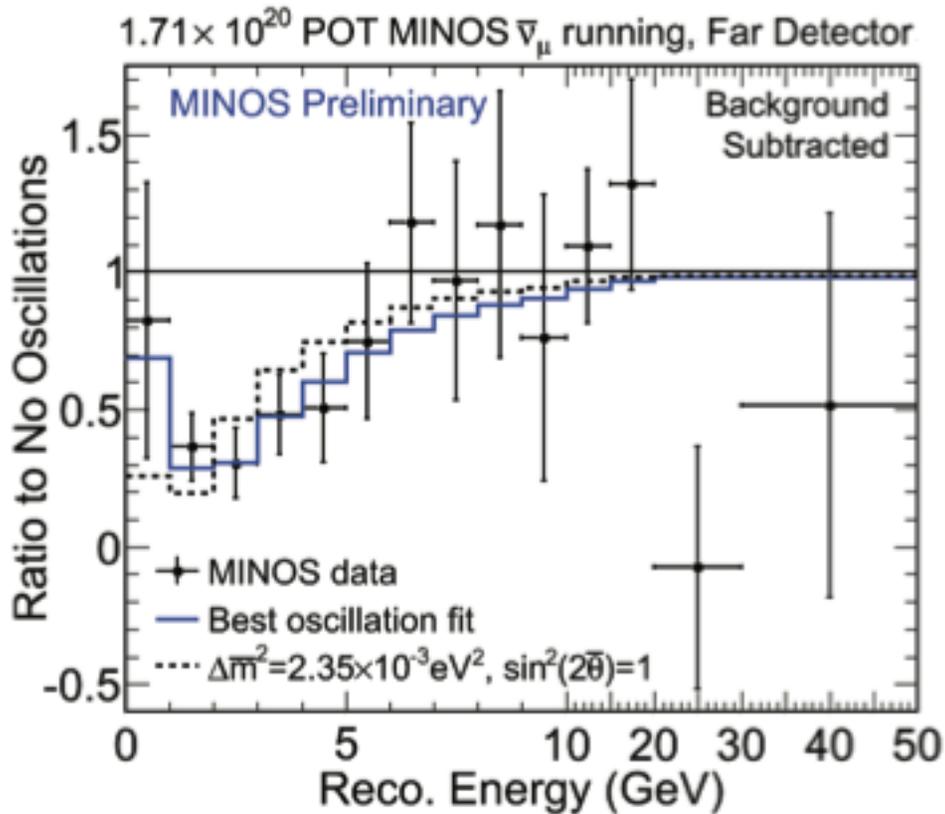

Assuming that the 3 light neutrinos are mostly active and the N heavy neutrinos are mostly sterile.

Future Experiments

- More MiniBooNE $\bar{\nu}$ Data (15E20 POT)
- MicroBooNE
 - Address low energy excess
- NOvA: 2 near detectors?
- LBNE: Look at high energy!
- Few ideas under consideration:
 - Build a MiniBooNE like detector (or a 2nd MicroBooNE detector at 200m) (LOI arXiv:0910.2698)
 - A new search for anomalous neutrino oscillations at the CERN-PS (arxiv:0909.0355v3)
 - Redoing a stopped pion source at ORNL (OscSNS - <http://physics.calumet.purdue.edu/~oscsns/>)

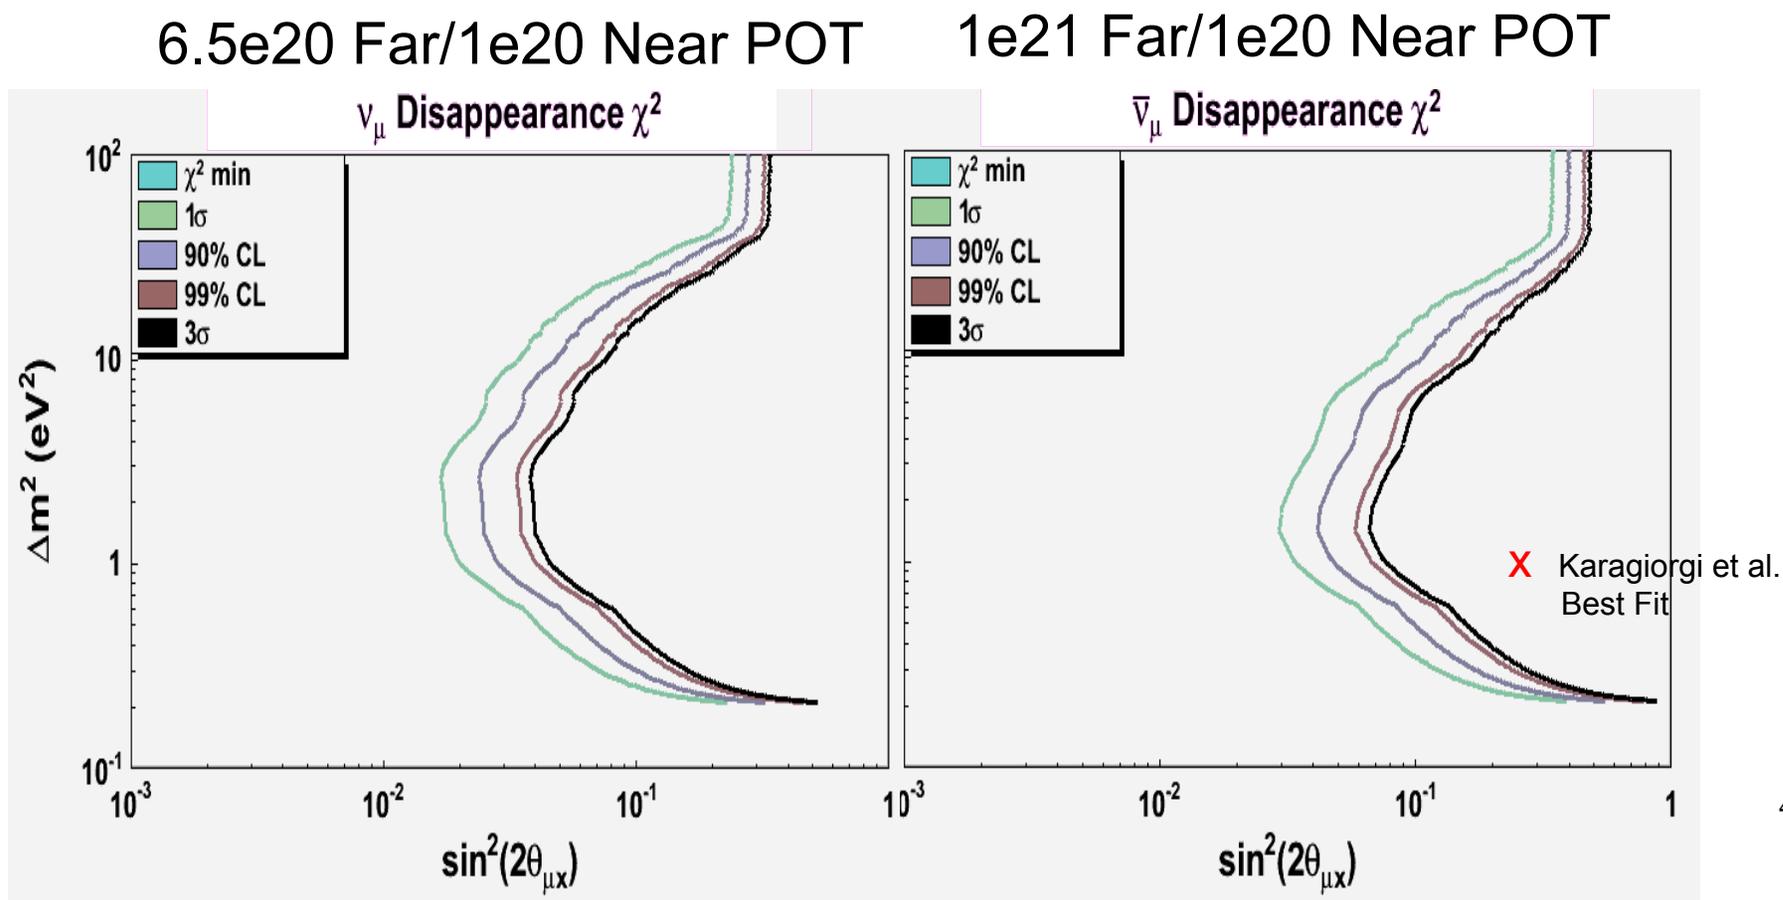

BooNE: Near Detector at ~200 m

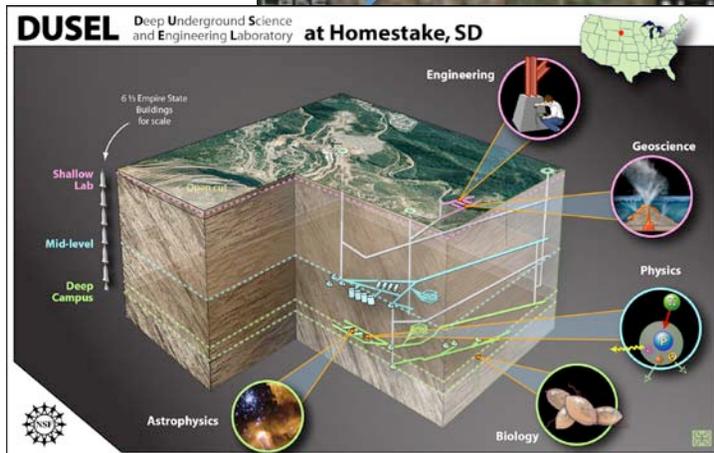

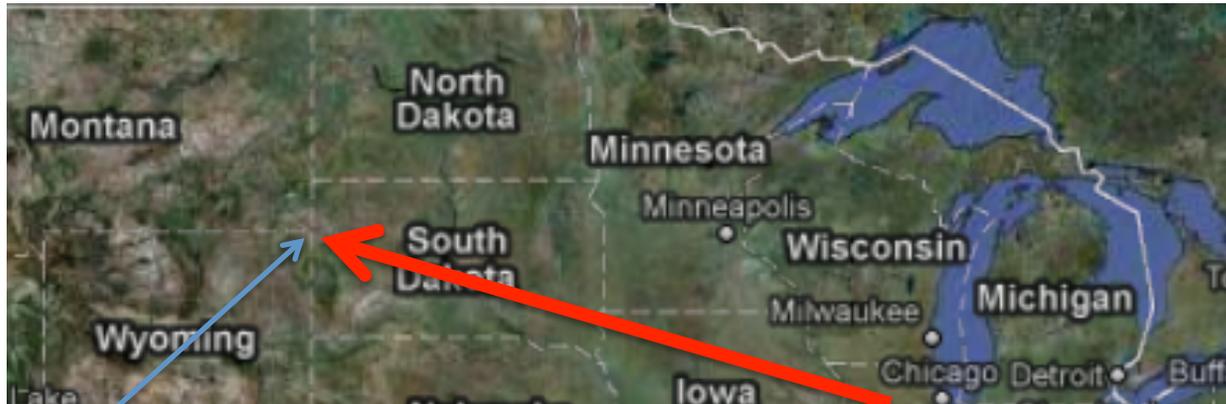

BooNE

- Much better sensitivity for ν_μ & $\bar{\nu}_\mu$ disappearance
- Look for CPT violation ($\nu_\mu \rightarrow \nu_\mu \neq \bar{\nu}_\mu \rightarrow \bar{\nu}_\mu$)

LBNE (~1300 km)

- 1GeV protons on Hg target (1.4MW)
- Free source of neutrinos
- Well understood flux of neutrinos

OscSNS

$$\bar{\nu}_\mu \rightarrow \bar{\nu}_e \Delta(L/E) \sim 3\% ; \bar{\nu}_e p \rightarrow e^+ n$$

$$\nu_\mu \rightarrow \nu_e \Delta(L/E) \sim 3\% ; \nu_e C \rightarrow e^+ N_{gs}$$

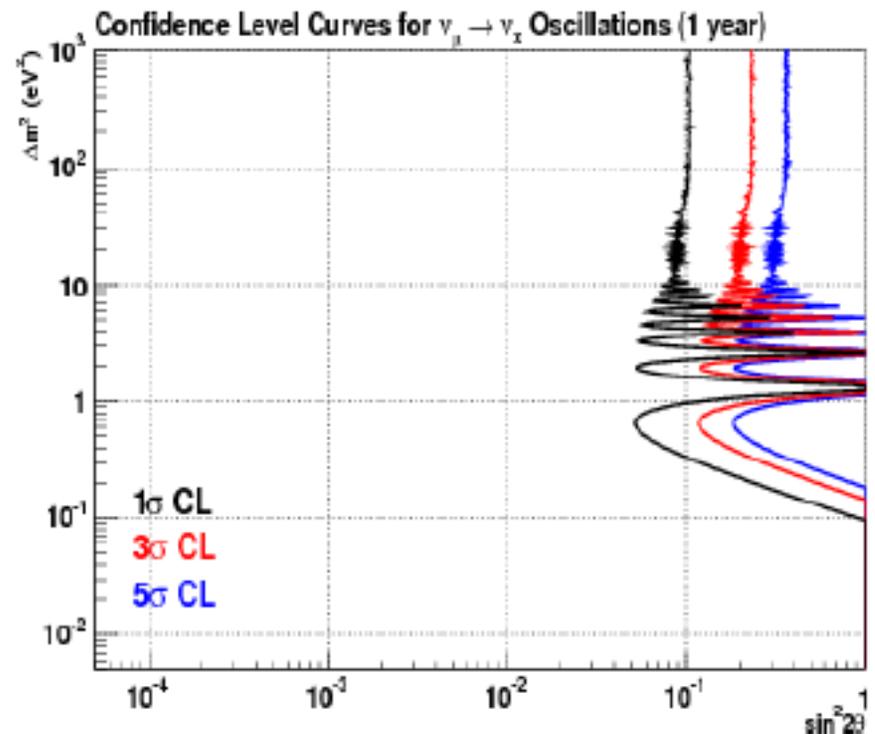

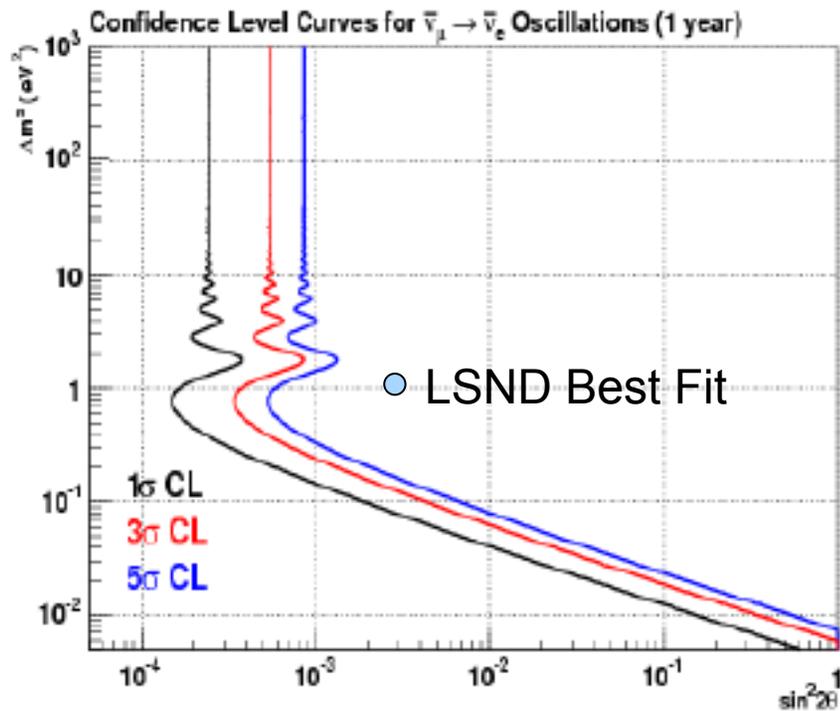

$$\nu_\mu \rightarrow \nu_s \Delta(L/E) < 1\% ; \text{Monoenergetic } \nu_\mu ! ; \nu_\mu C \rightarrow \nu_\mu C^*(15.11)$$

$$\bar{\nu}_\mu \rightarrow \bar{\nu}_s ; \bar{\nu}_\mu C \rightarrow \bar{\nu}_\mu C^*(15.11)$$

OscSNS would be capable of making precision measurements of $\bar{\nu}_e$ appearance & ν_μ disappearance and proving, for example, the existence of sterile neutrinos! (see Phys. Rev. D72, 092001 (2005)).

OscSNS

- $\bar{\nu}_e$ appearance (left) and ν_μ disappearance sensitivity (right) for 1 year of running (for 60m)

Conclusions

- The MiniBooNE data are consistent with $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillations at $\Delta m^2 \sim 1 \text{ eV}^2$ and consistent with the evidence for antineutrino oscillations from LSND.
- The MiniBooNE $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ oscillation allowed region appears to be different from the $\nu_\mu \rightarrow \nu_e$ oscillation allowed region, although nuclear effects could possibly explain this difference.
- The world antineutrino data fit well to a 3+1 oscillation model with $\Delta m^2 \sim 1 \text{ eV}^2$. This model predicts large $\bar{\nu}$ disappearance. (Other possibilities include, e.g., sterile ν decay and Lorentz Violation.)

The world neutrino + antineutrino data fit fairly well to a 3+2 oscillation model with CP Violation, although there is some tension.

- MINOS, IceCube, NOvA (two detectors), LBNE, BooNE at FNAL (two oil Detectors or two LAr detectors), ICARUS at CERN, or OscSNS at ORNL could measure neutrino oscillations with high significance ($>5\sigma$) and prove that sterile neutrinos exist!

All $\bar{\nu}_e$ background estimates assume a 20% error. Note that the $\bar{\nu}_e/\bar{\nu}_\mu$ ratio determines the background!

LSND Paper: A. Aguilar et al., Phys. Rev. D 64, 112007 (2001); (uses **MCNP**)

Zhemchugov Poster1: **FLUKA** $\bar{\nu}_e/\bar{\nu}_\mu$ ratio presented at the ICHEP 2010 Conference, Paris

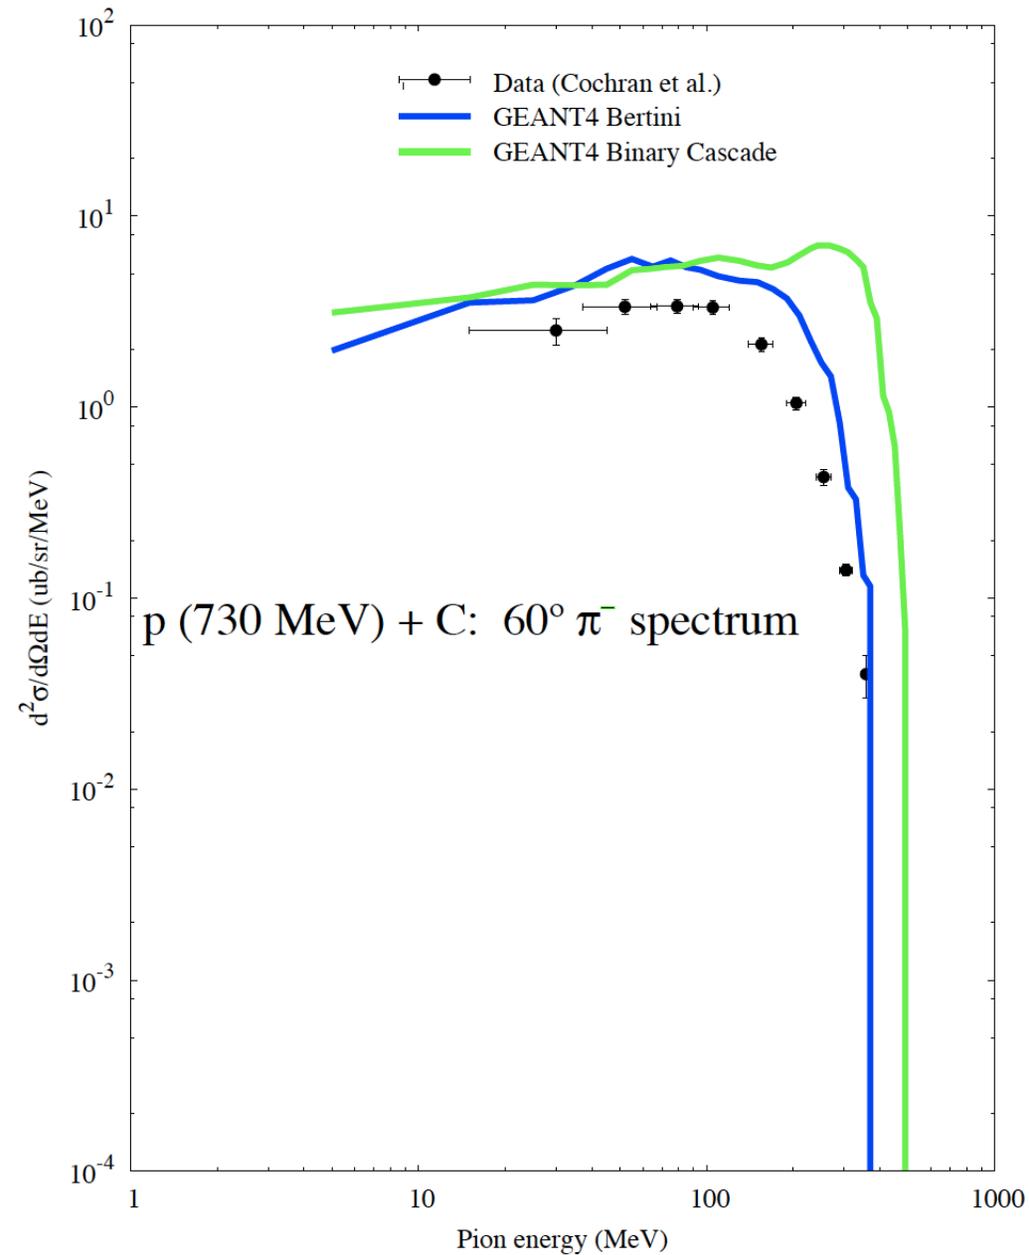

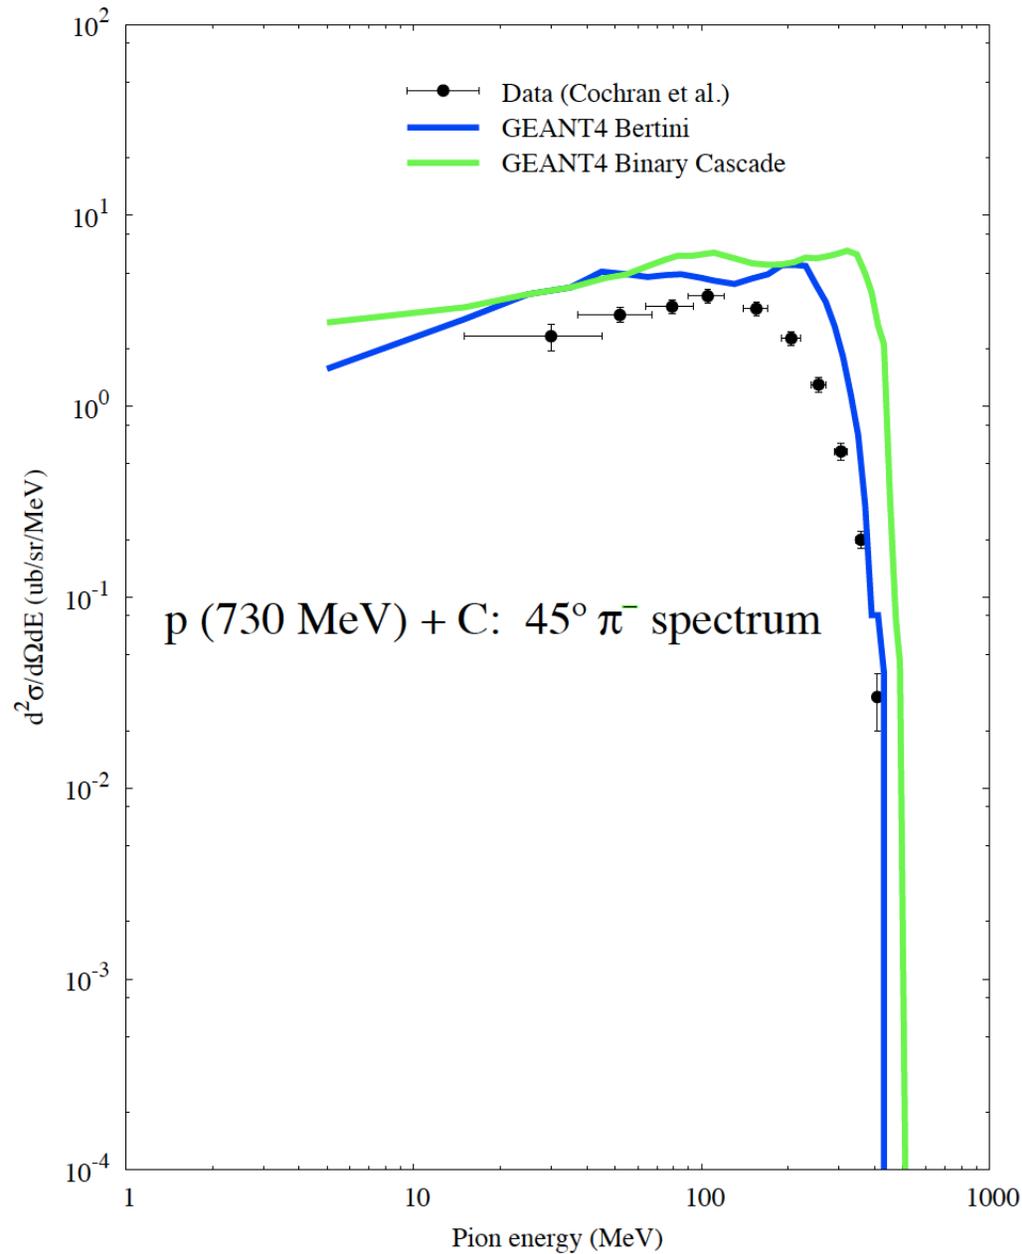

Zhemchugov Poster2: **GEANT4** $\bar{\nu}_e/\bar{\nu}_\mu$ ratio presented at the ICHEP 2010 Conference, Paris

Zhemchugov Seminar: **FLUKA** $\bar{\nu}_e/\bar{\nu}_\mu$ ratio presented at CERN on September 14, 2010

Although the analysis of Zhemchugov et al. is not fully understood or endorsed, their $\bar{\nu}_e/\bar{\nu}_\mu$ ratios agree reasonably well with the published LSND results.

Note that LSND measures the correct rate of $\bar{\nu}_\mu p \rightarrow \mu^+ n$ interactions, which confirms the π^- production and background estimates. Note also, that FLUKA & GEANT4 are not as reliable as MCNP at 800 MeV!

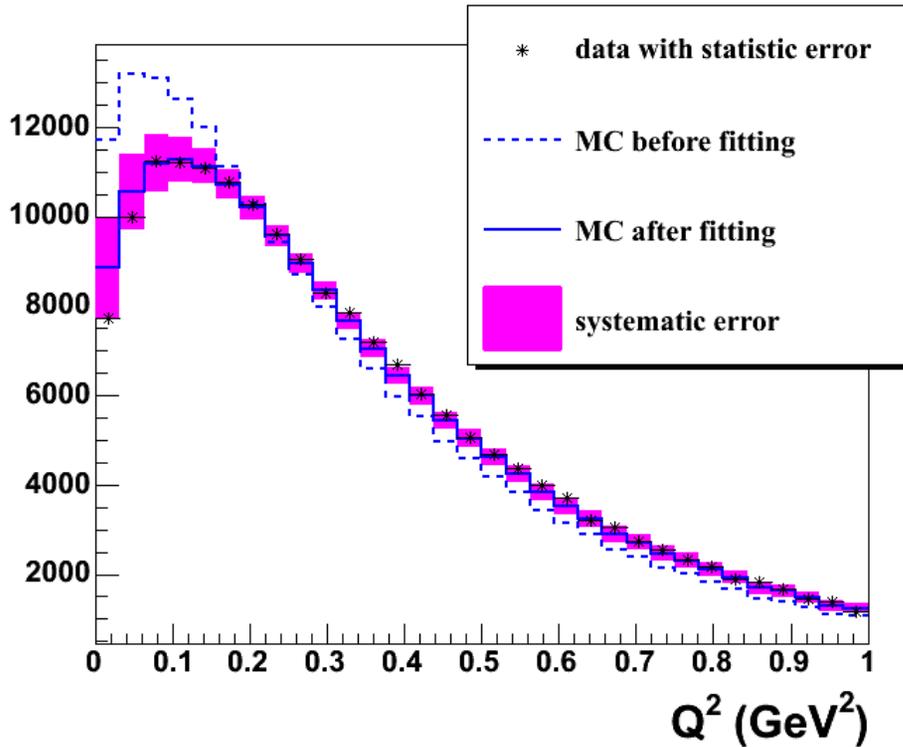

GEANT4 Overestimates π^- Production!

ν_μ CCQE Scattering

A. A. Aguilar-Arevalo et al., Phys. Rev. Lett. 100, 032301 (2008)

186000 muon neutrino events

From Q^2 fits to MB ν_μ CCQE data:

M_A^{eff} -- effective axial mass

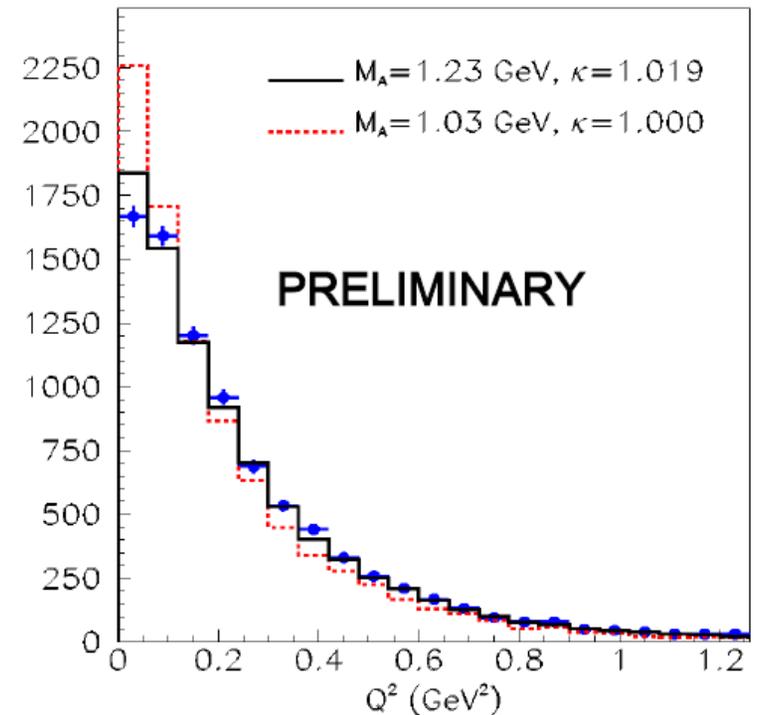

κ -- Pauli Blocking parameter

From electron scattering data:

E_b -- binding energy

p_f -- Fermi momentum

14000 anti-muon neutrinos

Fermi Gas Model describes CCQE

ν_μ data well

$$M_A = 1.23 \pm 0.20 \text{ GeV}$$

$$\kappa = 1.019 \pm 0.011$$

Also used to model ν_e and $\bar{\nu}_e$ interactions
